Introduction

Chapter 2

Literature Review

2.1 Overview

In 2014, over 6 million Canadians (15.6% of the population) were 65 years old or older. The number of older adults (65+) continues to increase; and by 2030, Statistics Canada expects there to be over 9.5 million adults over the age of 65, comprising 23% of Canadians [2]. Frequently, older adults who wish to age-in-place or in the comfort of their own home must be able to perform their activities of daily living (ADLs) while bearing multiple diseases and syndromes that come with age, such as frailty, impaired cognition, gait and balance problems [3]. These ADLs may include cooking, bathing, getting into and out of bed, and toileting all of which require complex coordination of the older adult's cognitive, physical, visual, and perceptual abilities (a complete list may be found in Table 2.1). Deficits in any of the categories mentioned can impair the older adult's ability to go about their day. However, it is typically only after an incident or hospitalization that an older adult is assessed for their ability to perform ADLs [4].

The current system presents an opportunity for proactive and preventative medicine through the use of in-home monitoring. Data obtained through monitoring can be used to track functional decline. With this information, older adults, along with their clinician, can plan early interventions and prevent future incidents and hospitalization.

Table 2.1: Complete list of Basic ADLs and Instrumental ADLs. Adapted from [5].

Category	Name	Description
Basic ADLs	Ambulating	Ability to move from one position to another and get around the house.
	Feeding	The ability to feed oneself.
	Personal Hygiene	The ability to maintain hygiene for oneself. Includes dental, nails and hair hygiene.
	Continence	The ability to put on clothes, shoes, pants, etc.
	Toileting	The ability to use the toilet appropriately and clean oneself after.
Instrumental ADLs	Transportation and Shopping	Ability to arrange transportation for oneself or drive. Also, the ability to procure groceries, clothing and any other daily necessities.
	Managing Finances	Ability to manage assets and pay the bills.
	Meal preparation	End-to-end ability to put a meal onto the table. Involves both purchasing of groceries, cooking, plating and brining to the dining table.
	Housecleaning and home maintenance	Cleaning kitchen after eating and keeping living areas reasonably clean and tidy. The ability to maintain the home and arrange repairs if needed.
	Managing communication with other	The ability to use phone and mail to communicate with others.
	Managing Medication	Ability to obtain medications and take them as directed.

To better understand the role of in-home monitoring, the diseases and conditions that older adults may face as they age must be understood. Accordingly, the next sections will be organized as follows: first, an overview of the disease or condition including its definition, prevalence and symptoms will be presented; next, current assessment tools for ADLs will be discussed; finally, current attempts at in-home monitoring for ADLs will be investigated as well as what data and how the data is being used.

2.2 Background for Diseases and Conditions in Aging

This section reviews the current literature on the disease and conditions associated that affect the ability to perform ADLs as older adults age. In terms of functionally being able to perform one’s ADLs, both physical and cognitive ability are required. Peter et al., in their exploration of ADLs, mention frailty and dementia as conditions limiting ADL performance [5]. In addition to physical and cognitive abilities, sensory decline with hearing, vision and vestibular function (associated with dizziness) occur as one ages [6]. Several chronic conditions may also be present in older adults such as cardiovascular disease including heart failure and ischemic heart disease; diabetes mellitus; osteoarthritis; and osteoporosis [6].

2.2.1 Frailty

Frailty is a syndrome present in 20-50% of the middle and older aged population (ages 50+ years) [7] and is associated with ageing and co-morbidities, but not caused by them [8]. Individuals with frailty are at “higher risk for adverse health outcomes such as illnesses, hospitalization, disability and mortality”. To define frailty, there are 2 models: the frailty phenotype and the frailty index [9]. The frailty phenotype (also known as the Fried’s Definition of Cardiovascular Health Study) defines frailty as meeting three out of five of the following criteria: “weakness, slowness, low level of physical activity, self-reported exhaustion and unintentional weight loss,” whereas the frailty index uses a comprehensive geriatric assessment to determine cumulative deficits [9].

2.2.2 Dementia

Worldwide, 47 million people live with dementia, and the number is only expected to increase. By 2050, it is projected that 131 million individuals will be living with dementia [10]. In the US, the prevalence of dementia in older adults above the age of 68 is 15% [10]. Dementia is an umbrella term describing a gradual decline in cognitive abilities in several domains to the point of impairing social or occupational function [10]. It involves a slow onset and gradual loss of memory, typically paired with the inability to retain new information and ability to perform daily activities [10]. Prior to diagnosing dementia, there is typically a long history of cognitive decline combined with mention of cognitive decline from close friends and family [10]. When diagnosing dementia, a common tool that is used is the Mini Mental State Examination (MMSE): a paper test that lists several simple tasks such as spelling a word backwards, and asking about the day of the week, etc. [11].

2.2.3 Hearing Loss

The prevalence of hearing loss increases with age and at around 85 years or older, about half of all older adults experience hearing impairments [12]. Hearing loss is associated with a decreased quality of life and impairs speech processing. Reduced conversational ability may lead to social isolation which is associated with depression and cognitive decline [6].

2.2.4 Vision Loss

Similar to hearing loss, the prevalence of vision loss increases with age. In the UK, it was found that 23% of older adults ages 85-89 had severe vision loss and this increases to 37% for older adults older than 90 years [13]. Older adults with vision loss are reported to have slower walking speeds and have difficulty doing physical activities [14]. Vision loss can also "predict cognitive decline and risk of dementia" [14].

2.2.5 Dizziness

In 2000, Tinetti et al., found that 24% of their sample American population over age 72 experience dizziness [15]. The cause of dizziness in the older pop-

ulation is multifactorial, but the most common cause is peripheral vestibular dysfunction (the part of the ear responsible for balance) [16]. As one ages, the number of vestibular hair cells and neurons decrease which impairs the older adult's ability to sense changes in orientation [16]. As a result, their balance and postural stability deteriorates and they are at higher risk of falling [16].

2.2.6 Heart Failure

Heart Failure affects at least 26 million people worldwide and the number of people affected continues to grow [17]. The American College of Cardiology (ACC) Foundation and American Heart Association (AHA) define Heart failure (HF) as “a complex clinical syndrome that results from any structural or functional impairment of ventricular filling or ejection of blood [18].” There are two types of HF: HF with reduced ejection fraction and HF with preserved ejection fraction. HF with reduced ejection fraction occurs at an ejection fraction $\leq 40\%$ and HF with preserved ejection fraction occurs at an ejection fraction $\geq 50\%$ [18]. Though patients with HF present with a variety symptoms, some include shortness of breath, lethargy, fatigue, reduced exercise tolerance, wheezing, and ankle swelling [19].

2.2.7 Ischemic Heart Disease

Ischemic heart disease (IHD) is also called coronary heart disease (CHD) or coronary artery disease (CAD) [20] and between the periods of 2003 to 2006 it was estimated that 17.6 million or 7.9% of Americans age 20 or older had CAD [20]. Similar to the other conditions, prevalence of IHD increases with age: in 2017 the National Health and Nutrition Examination Survey reported a prevalence of 30.6% in men and 21.7% in women over the age of 80 [21]. IHD manifests due to a condition called atherosclerosis which is a buildup of plaque in the blood vessels [20]. Atherosclerosis reduces the diameter of the blood vessel which reduces the supply of blood to an organ. The condition when an organ doesn't get enough blood and oxygen is referred to as ischemia. In the case of Ischemic Heart Disease, the heart does not receive enough blood and oxygen [20]. As a result, IHD may cause symptoms such as fatigue and angina pectoris which is the discomfort that is felt when the heart muscle does not get enough oxygen [20].

2.2.8 Diabetes Mellitus

Diabetes occurs when the body cannot control its blood sugar levels [22]. People who have diabetes are at risk of damaging blood vessels in their eyes, kidneys and nerves [22]. Diabetes mellitus can come in two main subtypes: type 1 diabetes mellitus (T1DM) or type 2 diabetes mellitus (T2DM) [22]. T1DM occurs due to the destruction of insulin producing beta-cells from an autoimmune process, while T2DM appears when cells develop a resistance to insulin and fail to use insulin that is being produced. The full extent of T2DM occurs when a cell's resistance to insulin overtakes the body's ability to produce insulin [22]. Diabetes affects 1 in 11 adults. 90% of adults have T2DM and the remaining 10% have T1DM. Onset for people with T1DM gradually increases from birth and peaks at ages 4 to 6 years and again from 10 to 14 years [22]. Signs and symptoms of diabetes include being overweight/obese, blurry vision, yeast infections, numbness, and neuropathic pain [22]. T1DM is diagnosed based on a history of "fasting glucose over 126 mg/dL, random glucose over 200 mg/dL, or hemoglobin A1C exceeding (HbA1C) 6.5%" [22]. The early stages of T2DM uses fasting glucose and HbA1C as well, but Sapra and Bhandari do not provide a specific level. A precursor to T2DM, prediabetes can be diagnosed with a glucose level of 100 to 125 mg/dL or a 2-hour post-oral glucose tolerance test (testing blood sugar levels one hour after ingesting 75 g of glucose dissolved into 250 ml to 300 ml of water [23]) glucose level of 140 to 200 mg/dL [22].

2.2.9 Osteoarthritis

Osteoarthritis affects approximately 27 million Americans [24] and onsets in a third of adults during the typical working age of 45-64 years [25]. There are about 315 million visits to the doctor, and 744 000 hospital admissions per year in the US for osteoarthritis. These figures add up to a total of 68 million days off work [26]. Osteoarthritis is the most common type of joint disorder. It is a disease characterized by the mechanical destruction and failure of a synovial joint [27]. In order of the most common location, the knee ranks first, followed by the hand and the hip [27]. High-risk factors or factors that greatly increase the chance of having osteoarthritis include obesity and previous joint injury [26]. Osteoarthritis typically presents as debilitating pain, and is accompanied by stiffness, reduced range of motion, joint instability, swelling, muscle weakness, and fatigue [27]. Clinical diagnosis is based on the

symptoms that the patient presents with such as pain, and functional limitations [27]. Additionally, diagnostic criteria such as those from the American College of Rheumatology may also be used [27, 28].

2.2.10 Osteoporosis

Osteoporosis is characterized by a reduction in bone mass and structural deterioration inside of the bone [29]. It is estimated that over 200 million people have osteoporosis and incidence increases with age [30]. Over the age of 80, it is estimated that 70% of people have osteoporosis [30]. This condition leads to an increased risk of bone fractures at all bone locations, with hip and vertebral fractures being historically associated with osteoporosis [29]. Typically, there is a long "latent period," where osteoporosis goes undetected, before it manifests clinically as a vertebral, rib or hip fracture [31]. One of the earliest symptoms of osteoporosis occurs as a result vertebral compression fractures [31]. The individual may experience acute back pain at rest or during activity such as bending, standing from a seated position and lifting an object [31]. Individuals with hip fractures experience pain and an inability to bear weight which leads to reduced functional status and quality of life [29]. In 2010, 2.7 million hip fractures occurred worldwide [29] and as one ages, the incidence of hip fractures increases exponentially [29].

2.3 Traditional Assessment of ADLs

The traditional assessment of ADLs often involves a pen and paper test. Some tools may require a trained clinician to ask the patient to perform some tasks related to the ADL and observe their performance [32]. Based on the criteria outlined in the assessment tool, a score is assigned and helps the clinician later identify deficits and plan care accordingly [33]. Other tools may require the clinician to check patient medical records, use direct observation or interview the patient directly to assign scores [34].

Pashmdarfard and Azad in their systematic review of ADL assessment tools identified 8 tools assessing Basic ADLs and 5 tools assessing Instrumental ADLs [32]. The Basic ADLs assessment tools are as follows:

- Barthel index
- Katz Index of Independence in ADLs

- Functional Independence Measure
- ADL Profile
- ADL Questionnaire
- Australian Therapy Outcome Measures
- Melbourne Low-Vision ADL Index
- Self-Assessment Parkinson's disease (PD) Disability Scale

And the Instrumental ADL assessment tools are as follows:

- Frenchay Activities Index
- ADL Profile Instrumental
- Lawton Instrumental ADL Scale
- Performance Assessment of Self-Care Skills
- Texas Functional Living Scale

2.3.1 Barthel index

There are 10 activities related to Basic ADLs that are assessed by the Barthel Index: bowels, bladder, grooming, toilet use, feeding, transfer, mobility, dressing, stairs, and bathing [35]. Total possible scores range from 0-20 with 20 being highly functional and 0 indicating high disability. Scores can be obtained through self-report, by proxy (reports from someone who is familiar with the individual), or through observation. A version of the Barthel Index used at Alberta Health Services is provided in Figure 2.1.

Barthel Index of Activities of Daily Living

Instructions: Choose the scoring point for the statement that most closely corresponds to the patient's current level of ability for each of the following 10 items. Record actual, not potential, functioning. Information can be obtained from the patient's self-report, from a separate party who is familiar with the patient's abilities (such as a relative), or from observation. Refer to the Guidelines section on the following page for detailed information on interpretation.

The Barthel Index	
<p><u>Bowels</u> 0 = incontinent (or needs to be given enemas) 1 = occasional accident (once/week) 2 = continent Patient's Score: ____</p>	<p><u>Transfer</u> 0 = unable – no sitting balance 1 = major help (one or two people, physical), can sit 2 = minor help (verbal or physical) 3 = independent Patient's Score: ____</p>
<p><u>Bladder</u> 0 = incontinent, or catheterized and unable to manage 1 = occasional accident (max once per 24 hours) 2 = continent (for over 7 days) Patient's Score: ____</p>	<p><u>Mobility</u> 0 = immobile 1 = wheelchair independent, including corners, etc. 2 = walks with help of one person (verbal or physical) 3 = independent (but may use any aid, e.g., stick) Patient's Score: ____</p>
<p><u>Grooming</u> 0 = needs help with personal care 1 = independent face/hair/teeth/shaving (implements provided) Patient's Score: ____</p>	<p><u>Dressing</u> 0 = dependent 1 = needs help, but can do about half unaided 2 = independent (including buttons, zips, laces, etc.) Patient's Score: ____</p>
<p><u>Toilet Use</u> 0 = dependent 1 = needs some help, but can do something alone 2 = independent (on and off, dressing, wiping) Patient's Score: ____</p>	<p><u>Stairs</u> 0 = unable 1 = needs help (verbal, physical, carrying aid) 2 = independent up and down Patient's Score: ____</p>
<p><u>Feeding</u> 0 = unable 1 = needs help cutting, spreading butter, etc. 2 = independent (food provided within reach) Patient's Score: ____</p>	<p><u>Bathing</u> 0 = dependent 1 = independent (or in shower) Patient's Score: ____</p>
<p>Total Score: ____</p>	

Scoring: Sum the patient's scores for each item. Total possible scores range from 0 – 20, with lower scores indicating increased disability. If used to measure improvement after rehabilitation, changes of more than two points in the total score reflect a probable genuine change, and change on one item from fully dependent to independent is also likely to be reliable.

Figure 2.1: Alberta Health Services (AHS) adaptation of the Barthel Index [35]

2.3.2 Katz Index of Independence in ADLs

The Katz Index evaluates 6 categories for Basic ADLs: bathing, dressing, toileting, transfers, continence, and feeding for older adults. Though the Katz Index is binary (either independent or dependent), the evaluator is given 3 choices for each category and must select one for each: independence, intermediate dependence and full dependence [36]. Figure 2.2a shows the evaluation form a clinician would use. Adequacy or overall performance in the 6 functions is given as a grade (A, B, C, D, E, F, and other) based on the type of dependence. The description of these grades may be found in Figure 2.2b. The results of this assessment can be used to describe functional level at the onset of an illness such as hip fracture [36]. It may also be used to compare treatment effectiveness between a control and treatment group, acts as a guide for hospital admittance, as well as guide progress during therapy [36].

Name.....Date of evaluation.....

For each area of functioning listed below, check description that applies. (The word "assistance" means supervision, direction of personal assistance.)

Bathing—either sponge bath, tub bath, or shower.

<input type="checkbox"/> Receives no assistance (gets in and out of tub by self if tub is usual means of bathing)	<input type="checkbox"/> Receives assistance in bathing only one part of the body (such as back or a leg)	<input type="checkbox"/> Receives assistance in bathing more than one part of the body (or not bathed)
---	---	--

Dressing—gets clothes from closets and drawers—including underclothes, outer garments and using fasteners (including braces if worn)

<input type="checkbox"/> Gets clothes and gets completely dressed without assistance	<input type="checkbox"/> Gets clothes and gets dressed without assistance except for assistance in tying shoes	<input type="checkbox"/> Receives assistance in getting clothes or stays partly or completely undressed
--	--	---

Toileting—going to the "toilet room" for bowel and urine elimination; cleaning self after elimination, and arranging clothes

<input type="checkbox"/> Goes to "toilet room," cleans self, and arranges clothes without assistance (may use object for support such as cane, walker, or wheelchair and may manage night bedpan or commode, emptying same in morning)	<input type="checkbox"/> Receives assistance in going to "toilet room" or in cleaning self or in arranging clothes after elimination or in use of night bedpan or commode	<input type="checkbox"/> Doesn't go to room termed "toilet" for the elimination process
--	---	---

Transfer—

<input type="checkbox"/> Moves in and out of bed as well as in and out of chair without assistance (may be using object for support such as cane or walker)	<input type="checkbox"/> Moves in or out of bed or chair with assistance	<input type="checkbox"/> Doesn't get out of bed
---	--	---

Continence—

<input type="checkbox"/> Controls urination and bowel movement completely by self	<input type="checkbox"/> Has occasional "accidents"	<input type="checkbox"/> Supervision helps keep urine or bowel control; catheter is used, or is incontinent
---	---	---

Feeding—

<input type="checkbox"/> Feeds self without assistance	<input type="checkbox"/> Feeds self except for getting assistance in cutting meat or buttering bread	<input type="checkbox"/> Receives assistance in feeding or is fed partly or completely by using tubes or intravenous fluids
--	--	---

(a) Evaluation form from the Katz Index of Independence in ADLs [36]

The Index of Independence in Activities of Daily Living is based on an evaluation of the functional independence or dependence of patients in bathing, dressing, going to toilet, transferring, continence, and feeding. Specific definitions of functional independence and dependence appear below the index.

A — Independent in feeding, continence, transferring, going to toilet, dressing, and bathing.

B — Independent in all but one of these functions.

C — Independent in all but bathing and one additional function.

D — Independent in all but bathing, dressing, and one additional function.

E — Independent in all but bathing, dressing, going to toilet, and one additional function.

F — Independent in all but bathing, dressing, going to toilet, transferring, and one additional function.

G — Dependent in all six functions.

Other — Dependent in at least two functions, but not classifiable as C, D, E, or F.

(b) Grades for determining adequacy outlined in [36]

Figure 2.2: The Katz Index of Independence in ADLs [36]

2.3.3 Functional Independence Measure

The Functional Independence Measure (FIM) is frequently used for patients who have experienced stroke [37]. FIM is based off of the Barthel Index and contains 18 items that tests independence in "self-care activities, mobility, locomotion, communication, sphincter control, and cognition" [37]. Each item is rated from 1 (total assistance) to 7 (independent) for a total score that ranges from 18 to 126—a higher score indicates higher independence [37]. If the level of dependence can not be evaluated, then the lowest score of 1 is given [37]. Unfortunately, the FIM is proprietary and cannot be reproduced here [38].

2.3.4 ADL Profile

The ADL Profile was created to assess ADL function in head injured people whose deficits lie mostly with "complex home and community activities" [39]. Accordingly, 10 domains were chosen for assessment: personal hygiene, dressing, feeding, health care, meal preparation and home management, and use of public services, transportation, financial management and time management [39]. Tasks are devised for each domain and the clinician would observe the patient performing the task. Following the completion of a task the clinician would rate the patient on a 3-point ordinal scale with 0 indicating dependence and 2 indicating independence based on their ability to perform the 10 operations common to all of the tasks [39]. See Figure 2.3 for an example of a score sheet for the ADL Profile.

<div style="border: 1px solid black; padding: 5px; display: inline-block;"> OPERATION <div style="display: flex; flex-direction: column; align-items: center;"> <div style="border: 1px solid black; padding: 2px; margin-bottom: 2px;">Y</div> YES <div style="border: 1px solid black; padding: 2px; margin-bottom: 2px;">N</div> NO <div style="border: 1px solid black; padding: 2px;">-</div> non applicable </div> </div>		Vigilance, attention	learning disposition	Reception, analysis	storage of information	Anticipation and	goal formulation	Planning	Carrying out and	verification	Simple movement	Kinesthesia	Optic-spatial	organization	Dynamic	organization	Complex praxis
		HYGIENE	1 completes personal hygiene <input type="checkbox"/> sink <input type="checkbox"/> bath <input type="checkbox"/> shower														
2 performs grooming <input type="checkbox"/> teeth <input type="checkbox"/> underarms <input type="checkbox"/> shave <input type="checkbox"/> nails <input type="checkbox"/> hair																	
3 performs toileting (care of perineum, toilet use ...)																	
DRESSING	4 puts on/remove indoor clothing and shoes																
	5 puts on/remove outdoor clothing and footwear																
	6 puts on/remove aids/ devices/ accessories																

Figure 2.3: Example of a score sheet for some tasks in the ADL profile [39]. Columns show the operations for each of the tasks.

Since Dutil et al's 1990 paper on the ADL profile, several other sources seem to have indicated that there have been some updates to the ADL Profile. Notably, the scoring system has expanded to a 4-point ordinal scale with 0 being independent and 3 being completely dependent [32, 40]. Furthermore the assessment includes a questionnaire for 3 items that are assessed through

a semi-structured interview with the person or their caregiver(s) [32, 40].

2.3.5 ADL Questionnaire

The ADL Questionnaire was developed for individuals with Alzheimer’s Disease. It is applicable to a wide range of dementia syndromes and can be used to track functional decline over time [41]. It assess six areas: ”self-care, household care, employment and recreation, shopping and money, travel, and communication” [41]. The primary caregiver assigns a score from 0 (no problem) to 3 (unable to perform) for each areas by comparing current level of ability to the level of ability before the onset of dementia” [41]. Impairment is then calculated by formula 2.1 (Note that all scores with ”9” are excluded because either the patient has never done the activity or the caregiver doesn’t know):

$$\text{Functional Impairment} = \frac{\text{Sum of all ratings}}{3 * \text{total number of items rated}} * 100\% \quad (2.1)$$

Impairment is the rated by ranges: 0-33% indicates none to mild impairment, 34-66% indicates moderate impairment and > 66% indicates sever impairment. An excerpt of the questionnaire is provided in Figure 2.4

APPENDIX. Activities of Daily Living Questionnaire (ADLQ)
Instructions: circle one number for each item

1. Self-care activities

A. Eating

- 0 = No problem
- 1 = Independent, but slow or some spills
- 2 = Needs help to cut or pour; spills often
- 3 = Must be fed most foods
- 9 = Don't know

B. Dressing

- 0 = No problem
- 1 = Independent, but slow or clumsy
- 2 = Wrong sequence, forgets items
- 3 = Needs help with dressing
- 9 = Don't know

C. Bathing

- 0 = No problem
- 1 = Bathes self, but needs to be reminded
- 2 = Bathes self with assistance
- 3 = Must be bathed by others
- 9 = Don't know

D. Elimination

- 0 = Goes to the bathroom independently
- 1 = Goes to the bathroom when reminded; some accidents
- 2 = Needs assistance for elimination
- 3 = Has no control over either bowel or bladder
- 9 = Don't know

E. Taking pills or medicine

- 0 = Remembers without help
 - 1 = Remembers if dose is kept in a special place
 - 2 = Needs spoken or written reminders
 - 3 = Must be given medicine by others
 - 9 = Does not take regular pills or medicine **OR** Don't know
-

Figure 2.4: Excerpt of the questions asked in the ADL questionnaire [41]

2.3.6 Australian Therapy Outcome Measures

The Australian Therapy Outcome Measures (AuTOM) is based on the UK Therapy Outcome Measures [42] and is used for evaluating therapy outcome measures across speech pathology, occupational therapy and physiotherapy. A core scale was developed with categories of impairment of structure or function, activity limitations, participation restriction and well-being each rated from 0 (most impairment) to 5 (no impairment). ADLs seem to reside in the occupational therapy domain which have 12 domains [42]:

1. learning and applying knowledge
2. self-care
3. functional walking and mobility
4. domestic life: inside house
5. upper limb use
6. domestic life: outside house
7. carrying out daily life tasks and routines
8. interpersonal interactions and relationships
9. transfers
10. work, employment and education
11. using transport
12. community life, recreation, leisure and play

2.3.7 Melbourne Low-Vision ADL Index

The Melbourne Low-Vision ADL Index was created to address the need to assess the ADL performance of individuals with vision impairment [43]. The index contains both task-based observational rating as well as questionnaire self-reported rating. For both ratings a scale of 0 (unsatisfactory) to 4 (satisfactory) was used. For the task-based observational rating, standardized descriptions at each score were developed to reduce the variability. Performance was evaluated based on speed, accuracy and independence and it was suggested that the evaluator time the task to better assess speed of execution [43]. The list of tasks is shown in Table 2.2.

2.3.8 Self-Assessment PD Disability Scale

The Self-Assessment PD Disability Scale is a self-report scale that bases its assessment on the degree of PD's interference on the individual's daily life [44]—and not on the "amplitude of tremors, or speed of foot tapping" [44]. Accordingly, the individual themselves should know PD's degree of interference on their daily life. There are a total of 24 items on the questionnaire with 11 assessing gross mobility and 13 assessing fine coordination. The individual is asked to rate themselves on a 5-point scale with 1 indicating no interference and 5 indicating maximum interference from PD [44]. The total score ranges from 24 to 120 with higher scores indicating higher disability [44]. The full list of items can be found in Table 2.3.

Table 2.2: Observational and questionnaire items in the Melbourne Low-Vision ADL Index [43]

Observational	Questionnaire
Reading newspaper print	Eating
Reading newspaper headlines	Bathing
Reading a letter with typed print	Dressing
Using a telephone book	Grooming
Reading an account	Mobility
Reading a medicine label	Housework
Reading packet labels	Shopping
Recognizing faces	Preparing meals
Using a telephone	Managing medication
Writing a check	
Identifying coins	
Pouring	
Naming colors	
Buttoning a shirt	
Threading a sewing needle	
Telling the time: wrist watch	
Telling the time: wall clock	
Reading a digital display	

Table 2.3: Items for the Self-Assessment PD Disability Scale [44]

Gross Mobility	Fine Coordination
Getting out of bed	Brushing teeth
Getting out of chair	Washing
Walking around home	Opening tins
Walking outside, eg. to shops	Pouring milk from bottle
Traveling by public transport	Making cup of tea
Walking up stairs	Holding cup and saucer
Walking downstairs	Washing and drying dishes
Getting into bath	Using knife and fork
Getting out of bath	Inserting electrical plug
Getting undressed	Dialing telephone
Picking up object from floor	Holding and reading newspaper
	Writing letter
	Getting dressed

2.3.9 Frenchay Activities Index

The Frenchay Activities Index (FAI) was created with 2 goals: first to "provide accurate information for pre-morbid lifestyle for individuals with stroke" and second "record changes in activities following stroke, at specific intervals" [45]. Through factor analysis, 3 factors were identified: "domestic chores", "leisure/work" and "outdoor activities" [45]. The assessment is questionnaire-based and includes 15 items that represent these 3 factors. Each item is given a score of 1 to 4 with 4 indicating more activity. The questionnaire is shown in Figure 2.5.

<i>Activities Index</i>	
<i>During previous 3 months</i>	
<i>Activity</i>	<i>Code</i>
___ Preparing main meals	1 = Never
___ Washing-up	2 = Under once weekly
	3 = 1-2 times a week
	4 = Most days
___ Washing clothes	1 = Never
___ Light housework	2 = 1-2 times in 3 months
___ Heavy housework	3 = 3-12 times in 3 months
___ Local shopping	4 = At least weekly
___ Social outings	
___ Walking outdoors over 15 min	
___ Pursuing active interest in hobby	
___ Driving a car/travel on bus	
<i>During previous 6 months</i>	
___ Outings/car rides	1 = Never
	2 = 1-2 times in 6 months
	3 = 3-12 times in 6 months
	4 = At least weekly
___ Gardening	1 = None
___ Household and/or car maintenance	2 = Light
	3 = Moderate
	4 = All necessary
___ Reading books	1 = None
	2 = 1 in 6 months
	3 = Less than 1 a fortnight
	4 = Over 1 a fortnight
___ Gainful work	1 = None
	2 = Up to 10 h/week
	3 = 10-30 h/week
	4 = Over 30 h/week
Total ____; Factor 1 ____; Factor 2 ____; Factor 3 ____.	

Figure 2.5: The questionnaire used in the Frenchay Activities Index.

2.3.10 ADL Profile Instrumental

The ADL Profile Instrumental v2 is an updated version of the ADL Profile designed specifically to assess Instrumental ADLs in patients with Traumatic Brain Injury [40]. The scoring system uses a 5-level ordinal scale to finely rate independence [40]. Rather than a separate task for each category of evaluation, a single scenario was given to the patient to assess a total of 8 categories: 6 related to the goal of preparing a meal including "dressing to go outdoors, going to the grocery store, shopping for food, preparing a hot meal for guests, having a meal with guests, and cleaning up after the meal" and 2 related to complex single tasks including "obtaining information, making a budget" [40]. In total, there are 29 scores for 5 tasks with 4 operations and 3 tasks with 3 operations [40]. The scenario prompt involved the following script followed by observation of the patient performing the task:

"We would like to know how you manage in your everyday activities, that is, activities that you generally do inside and outside of your home. More specifically, we would like to know, following your accident, if any changes have occurred in your ability to carry out your everyday tasks. Without knowing it, you invited my assistant and me to have lunch with you. Please get ready to receive us. We will assume any incurred expenses for a maximum of \$20. Can you tell me in your own words what I have just explained to you? Would you agree to do this? Can you now tell me in your own words what you are going to do?" [40]

2.3.11 Lawton Instrumental ADL Scale

The Lawton Instrumental ADL Scale was made for older adults and assesses 8 items: telephoning, shopping, food preparation, housekeeping, laundering, use of transportation, use of medicine, and financial behavior [46]. Unlike some of the other scales, there is a distinction in the scoring system between males and females. Males are rated on a 5-point scale whereas females are rated on a 8-point scale. Each item assessed has score of 1 for being able to or somewhat able to perform the task (see Figure 2.6), a score of 0 would indicate that the older adult is unable to perform the task. Women are assessed on all 8 items whereas men are assess on a subset of the items since the "list of representative activities is is smaller" [46]. The list for men include telephoning, shopping, use of transportation, use of medicine, and financial behavior. The Lawton IADL Scale provides a snapshot of what services or treatments the older adult needs (or does not need) and can be re-applied at periodic intervals to update treatment goals [46].

Score	Male % Correct	% Error		Score	Female % Correct	% Error		Score	Male % Correct	% Error		Score	Female % Correct	% Error
	64	5.2	A. Ability to use telephone		68	4.8							41	6.0
1			1. Operates telephone on own initiative—looks up and dials numbers, etc.	1								1		
1			2. Dials a few well-known numbers.	1								1		
1			3. Answers telephone but does not dial.	1								0		
0			4. Does not use telephone at all.	0				27	4.1		F. Mode of Transportation	30	10.0	
	15	5.2	B. Shopping		15	3.0		1			1. Travels independently on public transportation or drives own car.	1		
1			1. Takes care of all shopping needs independently.	1				1			2. Arranges own travel via taxi, but does not otherwise use public transportation.	1		
0			2. Shops independently for small purchases.	0							3. Travels on public transportation when assisted or accompanied by another.	1		
0			3. Needs to be accompanied on any shopping trip.	0				0			4. Travel limited to taxi or automobile with assistance of another.	0		
0			4. Completely unable to shop.	0							5. Does not travel at all.	0		
			C. Food Preparation		20	2.4		0			G. Responsibility for own Medications		38	9.5
			1. Plans, prepares and serves adequate meals independently.	1				0			1. Is responsible for taking medication in correct dosages at correct time.	1		
			2. Prepares adequate meals if supplied with ingredients.	0				35	4.1		2. Takes responsibility if medication is prepared in advance in separate dosages.	0		
			3. Heats and serves prepared meals, or prepares meals but does not maintain adequate diet.	0				1			3. Is not capable of dispensing own medication.	0		
			4. Needs to have meals prepared and served.	0				0						
			D. Housekeeping		51	7.1		0			H. Ability to Handle Finances.		52	10.0
			1. Maintains house alone or with occasional assistance (e.g., "heavy work-domestic help").	1				54	5.2		1. Manages financial matters independently (budgets, writes checks, pays rent, bills, goes to bank), collects and keeps track of income.	1		
			2. Performs light daily tasks such as dish-washing, bedmaking.	1				1			2. Manages day-to-day purchases, but needs help with banking, major purchases, etc.	1		
			3. Performs light daily tasks but cannot maintain acceptable level of cleanliness.	1							3. Incapable of handling money.	0		
			4. Needs help with all home maintenance tasks.	1				1						
			5. Does not participate in any housekeeping tasks.	0				0						
Rep. = .96	N = 97			Rep. = .93	N = 168			Rep. = .96	N = 97			Rep. = .93	N = 168	

Figure 2.6: The Lawton Instrumental ADL Scale, the blank "score" column shows the items that males are not assessed on [46].

2.3.12 Performance Assessment of Self-Care Skills

The Performance Assessment of Self-Care Skills (PASS) is a performance-based observational tool in which the clinician asks the patient to perform the required task for each of the ADLs assessed and evaluates their performance [32]. PASS assesses an individual's ability to perform ADLs by judging 3 parameters: independence, safety and adequacy. There are concrete guidelines and identifiers mentioned for scoring each parameter in Performance Assessment of Self-Care Skills [47]. For instance, the safety category has a maximum score of 3. At a score of 3, there are no risks observed; at a score of 2, there are minor risks observed, but no assistance is needed; at a score of 1, there are obvious risks to safety and assistance is required to complete a task; Finally, at a score of 0, there are risks to safety of such severity that the task had to be stopped. PASS is used around the world; has been translated to multiple languages including Spanish, Hebrew and Mandarin; has a test-retest reliability of 89%-90%; and an inter-observer agreement of 96%-97% [48] making it a reliable tool for assessing ADLs. However, as much as the PASS is reliable and comprehensive, it is also time-consuming and may be strenuous for the older adults [32].

2.3.13 Texas Functional Living Scale

The Texas Functional Living Scale is a performance-based assessment tool that was created to evaluate the IADL ability of individuals with cognitive impairment. 15 to 20 minutes are required to evaluate 21 items that target 5 functional areas: Dressing, Time, Money, Communication and Memory [49]. The minimum score for each item is 0, and the maximum score varies depending on the item. Altogether, the maximum score attainable is 52, with "higher scores indicating better performance" [49]. Examples of items on the Texas Functional Living Scale is shown in Figure 2.7.

2.3.14 Summary

Several key assessment tools for BADLs and IADLs have been discussed. Table 2.4 summarizes the category of ADL it assesses, what condition it is used for primarily, method of assessment as well as the length of assessment.

Domain	Points	Task
Dressing	5	1. Puts on jacket 2. Ties shoelaces
Time	15	1. States time on clock 2. Calculates time interval on clock 3. Sets clock 4. Locates current date on calendar 5. Reads calendar
Money	12	1. Counts money 2. Pays specified amount 3. Makes change 4. Writes sample check
Communication	12	1. Addresses envelope 2. Calls home 3. Looks up designated telephone number 4. Knows emergency telephone number 5. Describes how to make peanut butter and jelly sandwich
Memory	8	1. Takes out three pills from bottle when timer sounds 2. Recalls payee of check 3. Recalls amount of check
Total	52	

Figure 2.7: An example of some items on The Texas Functional Living Scale.

Table 2.4: Summary of the ADL Assessment tools discussed.

Name	Type	Condition	Method	Length
Barthel Index	BADL	N/A	Observation/Self Questionnaire	2-5 min [50]
Katz Index of Independence in ADLs	BADL	Older Adults or Chronically Ill	Observation Questionnaire	<5 min [51]
Functional Independence Measure	BADL	Stroke	Observation Questionnaire	30 min [52]
ADL Profile	BADL	Head Injured	Performance	30-60 min [53]
ADL Questionnaire	BADL	Alzheimer	Questionnaire	5-10 min [41]
Australian Therapy Outcome Measures	BADL	N/A	Observation Questionnaire	<5 min [54]
Melbourn Low-Vision ADL Index	BADL	Visually Impaired	Performance & Questionnaire	20 min [43]
Self-Assessment PD Disability Scale	BADL	Parkinson's	Self Questionnaire	5 min [55]
Frenchay Activities Index	IADL	Stroke	Questionnaire	5 min [56]
ADL Profile Instrumental	IADL	Head Injured	Performance	3 hours [40]
Lawton Instrumental ADL Scale	IADL	Older Adults	Self Questionnaire	10-15 min [57]
Performance of Self-Care Skills	IADL & BADL	Older Adults	Performance	3 hours [58]
Texas Functional Living Scale	IADL	Cognitive Impairment	Performance	15-20 min [59]

2.4 In-Home Monitoring of ADLs

Although traditional pen-and-paper assessment of ADLs can provide information regarding the current ability of an individual to perform ADLs, all only provide snapshots of their current ability and further tracking requires the patient to be present for the assessment. Furthermore, most involve an evaluator training period to ensure evaluator reliability, ratings are subjective, and performance-based evaluations are lengthy [58, 52, 40, 59]. There are also issues with measurement of functional performance in a clinical setting as opposed to an at-home setting that may skew observations. For example, it may be easier to stand-up from a firm higher chair in clinical settings than a soft sofa found at home [60]. In light of these challenges, this section will explore recent advances in monitoring technology for the evaluation of ADL ability. There will be a focus on the type of technology used, the parameters or metrics evaluated, the ADL it is used for and the criteria for assessing function. Information will be drawn primarily from two systematic reviews: Camp et al’s ”Technology Used to Recognize Activities of Daily Living in Community-Dwelling Older Adults” [60] and Gadey et al.’s ”Technologies for monitoring activities of daily living in older adults: a systematic review” [61].

2.4.1 Camp et al’s Tech Used to Recognize ADL in Community-Dwelling Older Adults

Camp et al.’s search identified a total of ”21 [distinct] technologies, including six wearable sensors, 13 environmental sensors, and two types of camera” [60]. The full list can be found in Table 2.6. These technologies were able to detect a total of 14 different ADLs, but no single technology system was able to detect all 14 [60]. Table 2.7 summarizes the ADLs detected as well as their level of granularity. There were 39 systems in total identified and most used the environment sensors. Only 3 out of the 39 systems used wearables. However, these wearable systems were able to recognize granular activities within ”feeding” such as drinking and using cutlery that was not included in the others [60].

Though the intent of the SR was to review technology that is able to detect if an ADL action has been completed and not test if the individual is functionally able to perform the ADL, there may be some correlations with assessment scales that may be drawn. For example, the activities that

technologies in Camp et al.’s review detect are present in the Barthel Index: bathing, dressing, feeding, grooming, mobility, stairs, toileting, and transfer. Sub-activities or finer-grained activities in the Barthel Index, such as activities to define feeding (cutting, or spreading butter), were not included as activities in these systems. According to Camp et al., there are few technologies that are able to recognize fine-skills such as cutlery use which have a ”large influence on more general activities such as feeding, and subsequently on overall health” [60]. There also may be concerns with privacy which prevent these technologies from advancing deeper into exploring the detection of these sub-activities. For example, humidity and sound sensors used to detect bathing, a sub-activity of grooming, may pose a privacy risk [60].

The systems identified recognize ADLs by using a series of interactions with the environment sensors and/or wearable sensors. For example, ”feeding” can be inferred by activity in the motion sensors in the kitchen/dining room, fridge door sensors, and power sensors attached to a microwave [60]. A full list of these interactions and accompanying ADL can be found in Table 2.8. Though these systems can recognize ADLs and is sufficient for the aim of monitoring functional decline by monitoring a decrease in ADL actions, Camp et al. suggest that methods to ”directly [assess] ADL performance” should be considered as it will allow for identification of ”exactly where an individual is having difficulty without the reliance on [time-consuming] traditional tests” [60].

Table 2.6: Types of technologies identified in Camp et al’s SR [60].

Category	Technology
Environment	Accelerometer
	Barometer
	Door Contact
	Force/Pressure
	Grid-Eye (Infrared array sensor)
	Humidity
	Hydro
	Light
	Motion
	Power Consumption
	Sound
	Temperature
	RFID Tag
Wearable	Wearable Accelerometer
	Wearable Altimeter
	Wearable Barometer
	Wearable Gyroscope
	Wearable Light
	Wearable Temperature
Camera	Depth Camera
	Video Camera

Table 2.7: Types of ADLs detected [60]. For Feeding there was separation in some studies between eating, meal preparation, drinking, and type of meal (breakfast, lunch, and dinner). For Grooming, some studies specified brushing teeth, showering, shaving, and hair styling. Finally for Social Interaction, most studies used the "front door usage," but some specified the time away from home, and the number of visits [60].

ADL Detected
Bed Usage
Dressing
Feeding
Grooming
Household
Medicine
Mobility
Recreation
Sleep
Social Interaction
Stair Usage
Toileting
Transferring
TV Usage

Table 2.8: How to detect each ADL based on the technology found in [60]

ADL Detected	Method
Bed Usage	Pressure sensors or accelerometers attached to the bed
Dressing	Room activity and door sensors attached to specific drawers/wardrobes
Feeding	Room activity, appliance use, or door sensors attached to cupboards within the kitchen area. Wearable sensor data
Grooming	Room activity, changes in temperature/humidity, water usage or specific door usage
Household	Water usage, room activity or appliance usage
Medicine	Door sensors attached to medicine cabinets
Mobility	Room activity or Wearable sensors
Recreation	Room activity or power consumption
Sleep	Room presence (but inactivity), typically the living room & bedroom
Social Interaction	Door sensors attached to the main property entrance
Stair Usage	Combined wearable sensors
Toileting	Room activity, specific door usage, water usage or accelerometers attached to the flush mechanism
Transferring	Room activity or pressure sensors or Wearable sensors
TV Usage	Power consumption/smart switch

2.4.2 Gadey et al’s Tech for Monitoring ADL in Older Adults

Compared to Camp et al.’s article which focusses on technology to detect the completion of an ADL, Gadey et al’s SR focusses more generally on the ”extent and diversity” of technologies that can be used for monitoring ADLs in older adults. From 16 articles, the SR yielded 48 technologies with categories of ”health-related technology, ambient appliance mounted, ambient location, motion-based, visual or interactive”. There is a further category of ”ambient” that is not mentioned explicitly in the article but appears as a category. After summarizing Table 4 in Gadey et al.’s article, 26 distinct technologies were found and are listed in Table 2.9 [61]. There may have been additional technologies identified in the SR, but were grouped under more general terms such as ”appliance sensors” [61].

There were both Basic ADLs and Instrumental ADLs assessed throughout the 16 articles. In terms of BADLs, walking, transferring, stair climbing, eating, bathing, sleeping, toileting, dressing, and grooming were monitored and assessed. Out of these, ”walking” was monitored and assessed the most with 11/16 articles [61]. There were 10 IADLs monitored and assessed: cooking, dishwashing, housework, managing medication, watching TV, phone use, and typing/writing. Out of these IADLs, cooking appeared the most at 6/16 articles [61].

The authors report that within the 16 articles selected wearables and Inertial Measurement Units (IMUs) were the most common technology applied and were used primarily for gait analysis. The accelerometer in the IMU was the most common in the activity recognition, and the entire IMU can be used for detecting postures and activity or inactivity. The article does not go into detail about the algorithms or methods used to detect the ADLs mentioned, but provides the suite of technologies (Wearable+Health, Wearable+Ambient, Wearables alone, etc.) used to detect certain ADLs. However, in the current state, it seems like the technologies and methods available can only detect activity and distinguish between general ADL classes [61]. An ideal monitoring solution would be able to detect changes in living patterns that may indicate early physical or cognitive decline [61]. It is not only the quantity of ADLs that needs to be monitored but also its quality (or how an ADL is being performed).

Table 2.9: Types of technologies identified in Gadey et al’s SR [61]. Each system, and not each technology, identified was given categories of health-related technology, ambient appliance mounted, ambient location, motion-based, visual or interactive. This Table is a best effort interpretation of the overlapping categorization of technologies. Where there was overlap (systems containing technology belonging to 2 or more categories), technologies that appeared in at least 2 different systems having the same categorization were grouped into that identifying category.

Category	Technology
Health-Related	Weight Scale BP measurement O2Sat Glucometer Heart Rate ECG Electrooculography Body Temperature Thermometer
Ambient Appliance Mounted	Electricity sensor Flow sensors Door Contact
Ambient Location	Force sensor Motion sensor Magnetic sensor
Ambient	Hygrometer (humidity) Microphones Pressure sensors Force Sensing Insole Barometer Ambient Temperature
Motion-Based	Accelerometer Gyroscope Magnetometer
Visual	Stereoscopic Camera
Interactive	Task List Alerts

2.5 Motivation

Both Camp et al. and Gadey et al. place an emphasis on the monitoring of the quality or performance of ADL. In Camp et al.'s case, doing so would allow a team of healthcare providers to pinpoint "exactly where an individual is having difficulty without the reliance on [time-consuming] traditional tests" [60]. In Gadey et al.'s case, the capability of ADL quality monitoring would allow for the early detection of physical or cognitive decline.

Though there are 6 IADLs that can be focussed on, refer to Table 2.1, the method and technology required to monitor and evaluate each is expected to differ. Also considering the scope and time constraints of this thesis, it is reasonable to approach the problem one ADL at a time. Accordingly, the IADL of cooking or meal preparation was chosen as the focus of this thesis since it presents an opportunity to monitor the quality or performance of an older adult wanting to age-in-place. Cooking is a "cognitive complex task, which requires multiple steps" [62] and coordination between physical and cognitive functionality. Moreover, cooking was identified to be critical in terms of sustaining a healthy lifestyle in older adults [63] and was found to be the highest ranked necessity "for independent living" in interviews with older adults [64]. Though cooking is essential, it is one of the most impacted IADLs after traumatic brain injury (TBI) meaning that decline in ability to cook may be indicative of cognitive decline. Some studies even suggest that cooking may be more "sensitive to patient deficit than traditional neurophysiological measures" such as head-injury [65]. Older adults also cook frequently, with 53% of older adults ages 65-80 reported to cook at home 6-7 days a week [66]. Despite the health benefits and enjoyment gained from cooking, cooking is fraught with risks [67]. There are safety concerns with the preparation of a hot meal and it poses risks such as "fires, burns" [64], injuries from improper knife use, and injuries from falls due to an unsafe kitchen environment [67] which monitoring and proactive intervention may have a role in preventing.

In pursuit of monitoring the cooking IADL, the next sections will be dedicated to scoping methodologies for monitoring and evaluating cooking. It will look at how cooking is monitored, the technologies involved, and the accompanying algorithms or models used to evaluate cooking.

2.6 Monitoring Cooking

Before cooking can be assessed, the first step in monitoring cooking is detecting the activity at a macro scale and separating it from all of the other IADLs and BADLs.

The literature already presents several different ways to detect meal preparation or cooking. Cook achieved this through the use of environment sensors such as motion sensors, door contact sensors, temperature sensors, light sensors, water flow sensors, stove-top burner use sensors and sensors on specific items [68]. The data collected from this system can then be used in a Naive Bayes Classifier, Hidden Markov Model (HMM), or Conditional Random Field, which are traditionally "robust in the presence of moderate amount of noise, are designed to handle sequential data, and generate probability distributions over the class labels" [68], to classify the activities. Cook also explored using the output probability distributions of each of these models as inputs to a boosted tree classifier to improve classification accuracy [68]. Logan and Healy used a modified form of AdaBoost with simple linear weak learners to distinguish meal preparation and eating through accelerometer, video capture, and audio capture data [69]. Sarma et al. used Long short-term memory (LSTM) to determine various ADLs from datasets containing motion sensors, door closure sensors and temperature sensors data [70]. Chibaudel et al. detected cooking by noting the physical location of the participant and their refrigerator usage through door sensors placed in the refrigerator and motion sensors in the kitchen [71]. Yordanova et al. used Decision Trees (DT), Computational Causal Behavior Models (CCBM), and HMM to process data from the full-scale SPHERE Smart Home system consisting of temperature sensors, humidity sensors, luminosity and motion sensors, water and electricity usage sensors, cameras, and door contact sensors to classify the preparation of a wide range of recipes as "cooking" [72].

Although there have been many studies involving the detection of the cooking ADL, few studies assess the quality of cooking and provide feedback to the user. One attempt at assessing quality involved quantifying the number of departures from a given task. Cook and Schmitter-Edgecombe used motion sensors, analog sensors for water and stove usage, open/shut sensors for the status of cabinets, and load sensors for the absent/present status of items to assess the quality of ADLs including meal preparation. If a correct sequence of tasks was done and if the task was done efficiently, then an activity is considered normal. Any significant departures from this "correct

sequence” and normal time required to complete each step was only left with a tag of ”anomalous” [73]. There is no further information with respect to how much of an anomaly the error was or what to do about it. Similarly, in Menghi et al.’s study, errors were identified in a series of tasks, but nothing was done to evaluate the severity of the error and no feedback was given to the user [71].

To address these shortcomings, Dawadi et al. performed an exploratory study to map smart-home sensors readings to ADL performance ratings based on a custom scale (Figure 2.8). The criteria for performance was based on whether ”important steps are skipped, performed out of sequence or performed incorrectly” (such as forgetting to close the fridge or leaving on a burner) [74]. Tasks completed inaccurately or inefficiently may be indicative of a cognitive health condition [74]. 8 activities were selected including sweeping and preparing microwavable soup. After completing each activity, each participant was rated by two observers based on the scale in Figure 2.8. Features were extracted from the sensor readings obtained during each activity such as duration of activity, sensor count, unrelated sensors, door sensor count, item sensor count, etc. Then, Support Vector Machines (SVMs) were trained on the features extracted and observer score labels to predict a score from sensor reading inputs. The authors note that though predicting task quality based on smart home sensor readings is possible, there is only moderate correlation between the predictions and the observer ratings [74]. The authors take the evaluation one step further and attempt to classify the cognitive health of the participants as cognitively healthy (CH), mild cognitive impairment (MCI) and dementia (D) based on the performance scores. Using SVM trained on the performance score and health status of the participant, the AUC score was calculated. For MCI vs. D was 0.56 and for D vs. CH it was 0.72 when considering all activities. This means that the classifier was almost no better than random guessing for the MCI vs. D case but had better predictability for the D vs CH case. Though it is possible to perform a ”limited health assessment” with task performance, the authors mention that the accuracy may be improved with additional tasks or features obtainable from sensors that can provide ”finer resolution” such as wearable sensors [74].

Based on the articles reviewed thus far, detecting the cooking activity alone may not be indicative of ADL cooking quality. However, detecting subtasks within the cooking activity and evaluating metrics or features such as steps skipped, performed out of sequence, and duration of these subtasks

Score	Criteria
1	Task completed without any errors
2	Task completed with no more than two of the following errors: non-critical omissions, non-critical substitutions, irrelevant actions, inefficient actions
3	Task completed with more than two of the following errors: non-critical omissions, non-critical substitutions, irrelevant actions, inefficient actions
4	Task incomplete, more than 50% of the task completed, contains critical omission or substitution error
5	Task incomplete, less than 50% of the task completed, contains critical omission or substitution error

Figure 2.8: Scoring Criteria for Dawadi et al.’s experiment.

can be correlated with a performance score (like in Dawadi et al. study [74]). Although Dawadi et al.’s approach was able to predict performance scores and distinguish between cognitively healthy and dementia patients, there are potentially two limitations. First Dawadi’s sensor suite provides only a coarse resolution of the appliance/item sensors which limited the subtasks that could be detected to item and appliance interactions. Thus, Dawadi et al. proposed searching for methods/sensors that may provide finer resolution such as wearables [74] as a next step. Second, features extracted from the sensor readings were used to predict performance scores that were custom-made. Though the scale is reasonable for evaluating performance, it may not be as well-validated as a scale devised in the observational traditional assessments for ADLs.

Following Dawadi et al.’s suggestion to search for methods/sensors that can detect finer-grained activities, there have been other attempts at the classification of the subtasks of cooking and other ADLs:

- Chen et al. used 5 IMUs each containing an 3D accelerometer and 3D gyroscope. 2 were placed at each wrist, 2 on each upper arm and one on the hip. These IMUs were used to detect 19 ADL subtasks: brush teeth, mixing powders, spreading butter/jam, eating with hands, eating with utensils, buttoning shirt/coat, put and take off the coat, moving items horizontally, reaching up, reaching down, washing dishes, chopping, pan stirring, serve on a plate, sweeping, vacuuming, wiping horizontal surface, wiping vertical surface, and folding clothes [75]. From each

axis of each sensor, 3 second windows were created and 4 statistical features were extracted: standard deviation, mean, slope (from linear regression), and auto-correlation (for repetitive actions). For feature selection, the authors used XGBoost since XGBoost has "better efficiency and controls for overfitting" [75] compared to the other models. After the features were selected, the Decision Tree, Random Forest, SVM, and XGBoost were tested to obtain the optimal model based on accuracy, recall, precision, and ROC AUC [75].

- Pan et al. detected fine-grained actions using a combination of structural vibration sensing and single-point electrical load sensing [76]. 8 activities were classified: kettle use, stove use, put on stove, use microwave, open/close microwave door, put down food, use vacuum, and footsteps. Segments of the signal from both types of sensors with significantly higher energy were extracted as events. Then, from each sensor within each event segment, the power spectral density was calculated, concatenated together and used as a feature vector [76]. SVM was chosen as the model for classification of the 8 activities mentioned previously.

2.7 Next Steps

Though there was some degree of success in the methods that the previous articles used to detect subtasks within ADLs, there may be some limitations. In Chen et al.'s approach, there may be too many sensors involved and may pose a challenge for older adults to put on and take off every day for continuous monitoring. Pan et al.'s usage of vibrational sensors is novel, but by design of environment sensors which continuously run, there may be ethical issues with control (autonomy) and the older adult will not be able to freely turn the system off. Furthermore, Pan et al.'s models are trained only on able-bodied individuals meaning there is no indication of performance on individuals with impairments. Judging from the limitations present in the articles scoped out so far, a first step in the endeavor of monitoring and evaluating cooking in older adults may be to develop a method that is practical, accurate and robust to variation caused by impairments in detecting these subtasks in real-time.

Toward the development of a practical and accurate method for detecting

cooking subtasks, it is hypothesized that a positional + IMU sensor placed on the dominant wrist in a wrist-watch form-factor would satisfy these ethical, practical and functional requirements. The older adult will be in full control of the system and can choose to not be monitored by taking off this watch satisfying autonomy [77]. Also, no cameras or video capture is used, alleviating concerns with privacy [78]. In regard to practicality, there is only one wearable involved and not 5 [75] making it easy for the older adult to wear the system. Finally, since certain subtasks occur only within certain areas in the kitchen, it is expected that the addition of the positional data will reduce misclassification from confounding motions in different locations that IMUs alone may not be able to separate. Positional data will also provide contextual information about interaction with appliances, or items within the kitchen without the need to instrument every item single item and appliance in the kitchen. For example, the opening action occurring near the fridge is indicative of opening the fridge as opposed to at the cabinet which means that the older adult opened the cabinet.

The rest of this thesis will work toward validating the performance and accuracy of the proposed IMU + positional sensor system for detecting cooking subtasks. Like in Chen et al's study, datasets of "atomic actions" or singular subtasks such as chopping, pan stirring, and washing dishes [75] will be created from an able-bodied individual with simulated impairments (eg. blind-fold to simulate visual impairments [79]). Feature extraction and feature selection will be performed to obtain a best set of features for predicting a subtask. Multiple models will be trained and evaluated for time-series classification including but not limited to, Random Forests, SVM, Convolutional Neural Networks (CNN) for stacked time series and LSTM. Subsequently, goal-based tasks, such as making a sandwich or preparing canned soup, which contain a collection of the aforementioned subtasks will be performed (normally and with simulated impairments) and used to validate the trained model. However, prior to this classification task there are 2 items that must be addressed: first, testing the proposed system and characterizing performance such as accuracy, and second determining the subtasks and goal-based tasks to be used for this thesis.

System Testing and Tuning at the Independent Living Suite

Chapter 4

Classification of Time Series Data

Chapter 5

Pilot Testing of Detecting Activities to make a Sandwich

Chapter 6

Data Collection for Fine-grained Activities

6.1 Selecting Cooking Tasks

To employ some of the time-series classification methods discussed in Chapter 4, a dataset of the proposed positional + IMU system is required. Chapter 2’s section on the traditional assessments of ADLs will serve as a basis for the selection of tasks to perform and collect data from. Of the assessments discussed, Table 6.1 summarizes the assessments with cooking tasks mentioned in its procedure.

Table 6.1: Cooking tasks in the Assessment tools for the IADLs.

Tool			Tasks
PASS			making soup with water/milk
			making muffins in the oven
			cutting up fruit
Self-Assessment PD Disability Scale			making a cup of tea
			inserting electrical plug
			pouring milk from bottle
			opening tins
			washing
Melbourne Low-vision ADL Index			preparing meals
Lawton Instrumental ADL Scale			plans, prepares and serves adequate meals independently
Frenchay Activities Index			preparing main meals
Texas Functional Living Scale			Describe how to make peanut butter and jelly sandwich

Of the assessments in Table 6.1, the cooking task(s) in the Melbourne Low-vision ADL Index, Lawton Instrumental ADL Scale, Frenchay Activities Index, and Self-Assessment PD Disability Scale are all questionnaires and as a result do not have concrete steps on how the task should be performed.

Futhermore, the Melbourne Low-vision ADL Index, Lawnton Instrumental ADL Scale and the Frenchay Activities Index only have general requirements for the cooking task such as the ability to "prepare meals," and "plans, prepares and serves adequate meals independently." These general cooking tasks may be useful in the evaluation of ADL ability in a questionnaire format by requesting the older adult to holistically consider their ability to cook, but may not be the best candidates when looking for fine-grained actions to extract.

The remaining 2 assessment tools, the Texas Functional Living Scale and Performance Assessment of Self-Care Skills (PASS), mention cooking task(s) that requires a clinician to evaluate. Upon closer inspection of the Texas Functional Living Scale, however, the individual is only required to describe the task and not actually perform it. The only candidate that has clear cooking tasks broken down into their fine-grained actions is the PASS and will be used as a reference for the experiment protocol and extraction of fine-grained tasks. 3 Cooking Scenarios are presented in the PASS: making soup with water/milk, making muffins in the oven, and cutting up fruit. The 3 cooking scenarios are shown in Figures 6.1-6.3.

Task # H23: IADL-C: Oven Use (Meal Preparation)		INDEPENDENCE DATA										SAFETY DATA	ADEQUACY DATA	
Assistive Technology Devices (ATDs) used during task: 1. 2. 3. Total # of ATDs used: _____		No Assistance	Verbal Supportive (Encouragement)	Verbal Non-Directive	Verbal Directive	Gestures	Task or Environment Rearrangement	Demonstration	Physical Guidance	Physical Support	Total Assist	INDEPENDENCE subtask scores	Unsafe Observations	PROCESS: Imprecision, lack of economy, missing steps QUALITY: Standards not met / improvement needed
Assist level →		0	1	2	3	4	5	6	7	8	9			
Subtasks	Subtask Criteria													
1	Reports correctly that muffins must be started first													
2	Sets oven temperature control correctly (as designated on instructions)													
3	Measures liquid correctly (amount listed on the package)													
4	Prepares muffins for oven correctly (stirs until blended; greases tin or puts in paper muffin cups; fills muffin cups about 2/3 full)													
5	Places food in oven correctly (uses mitt; if tremor is evident or if placing between two oven racks; does not allow skin to touch racks or inside of oven door)													
6	Removes food from oven correctly (uses mitt/holder; does not allow skin to touch racks or inside of oven door; removes + / - 5 minutes of shortest or longest suggested baking time; no indication of inadequately heated/ cooked food or burned food)													
7	Turns off oven promptly (before or immediately after removal of food)													
8	Removes muffins from tin onto plate correctly (uses mitt/holder and knife if tin still warm; lets tin cool and then removes muffins onto plate)													
9	Transports muffins to table correctly (uses cart if weakness, tremor or instability present; does not spill on floor)													

Figure 6.1: PASS Muffin Task [47]

Task # H25: IADL-C: Use of Sharp Utensils (Meal Preparation)		INDEPENDENCE DATA										SAFETY DATA	ADEQUACY DATA	
Assistive Technology Devices (ATDs) used during task: 1. 2. 3. Total # of ATDs used: _____		No Assistance	Verbal Supportive (Encouragement)	Verbal Non-Directive	Verbal Directive	Gestures	Task or Environment Rearrangement	Demonstration	Physical Guidance	Physical Support	Total Assist	INDEPENDENCE subtask scores	Unsafe Observations	PROCESS: Imprecision, lack of economy, missing steps QUALITY: Standards not met / improvement needed
Assist level →		0	1	2	3	4	5	6	7	8	9			
Subtasks	Subtask Criteria													
1	Obtains <u>correct</u> fruit from refrigerator (Apple)													
2	Selects <u>appropriate</u> <u>knife</u> (selects paring knife or other small knife)													
3	Cuts fruit into 8 parts, removes seeds, & removes <u>peel</u> <u>correctly</u> (8 pieces; seeds removed; peel removed)													
4	Transports <u>plate with fruit to table</u> <u>correctly</u> (does not carry knife along; uses cart if weakness, tremor, or instability present; does not spill on floor)													

Figure 6.2: PASS Fruit Task [47]

6.2 Fine-grained Task Extraction

The detail in which tasks can be broken down varies in literature. Human actions may be decomposed all the way into action primitives which is a body part + some motion (eg. right/left hand forward/backward) [118]. Fine-grained actions can be thought as being one level "coarser" than these action primitives and may combine action primitives to perform a small task (eg. cutting fruit, stir-frying, washing a fruit) [76]. A "coarser" level above fine-grained actions are coarse-grained actions and describe the activity that encompasses all of the fine-grained actions (eg. cooking, working). Although action primitives may be useful to consider when breaking down a task, the focus of the thesis is the evaluation of function and ability to perform tasks toward some goal. The detection of coarse-grained actions or activities have been successful in literature previously [68], but these coarse-grained actions are too general and do not provide insight into the functional quality of the cooking task. Thus, the focus of the task extraction will be at the "fine-grained" level.

For each cooking activity in the PASS, an experimental protocol will be developed based on the subtasks outlined in the task document. Although the PASS presents general steps to complete the task, there may sometimes be other actions, or "side-actions" involved in the task. For example, for the Cutting Fruit task in Figure 6.2, obtaining the fruit from the refrigerator would require the individual to perform OPEN_FRIDGE, GRAB_FRIDGE,

Task # H24: IADL-C: Stovetop Use (Meal Preparation)		INDEPENDENCE DATA										SAFETY DATA	ADEQUACY DATA	
Assistive Technology Devices (ATDs) used during task: 1. 2. 3. Total # of ATDs used: _____		No Assistance	Verbal Supportive (Encouragement)	Verbal Non-Directive	Verbal Directive	Gestures	Task or Environment Rearrangement	Demonstration	Physical Guidance	Physical Support	Total Assist	INDEPENDENCE subtask scores	Unsafe Observations	PROCESS: Imprecision, lack of economy, missing steps QUALITY: Standards not met / improvement needed
Assist level →		0	1	2	3	4	5	6	7	8	9			
Subtasks	Subtask Criteria													
1	Opens soup can <u>correctly</u> (cut is even, entire top is off or <1/2" is retained in one place)													
2	Removes/handles soup can lid <u>correctly</u> (lifts lid with knife; punches lid into can; does not cut finger)													
3	Pours/spoons soup into pan <u>without spilling</u> (no soup on Ct, counter, or floor)													
4	Adds liquid <u>correctly</u> (adds 1 can of water/milk; does not spill on self, floor)													
5	Places pan on <u>correct stove burner</u> (burner closest to pan size)													
6	Turns burner <u>on correctly</u> (manipulates knob for burner that soup is on or is placed onto later; sets control on medium to high)													
7	<u>Monitors soup adequately</u> (stirs; alters heat as necessary; soup does not stick on pan; checks to make sure soup temperature is hot rather than lukewarm to touch or taste or that soup boils/bubbles)													
8	Removes pan from burner when soup is still <u>hot</u> (steam can be seen rising from pan; checks to make sure soup temperature is hot rather than lukewarm to touch or taste)													
9	Turns burner off <u>promptly</u> (+/- 1 minute of removing soup from burner)													
10	Transports & pours soup into bowls <u>correctly</u> (uses mitt under pan or slides pan across counter for stability if weakness or tremor present; does not spill on floor; only minor drips on counter)													
11	Transports bowls to table <u>correctly</u> (uses mitt under bowl or uses cart if weakness, tremors, or instability present; uses bowl rim to carry; does not spill on floor)													

Figure 6.3: PASS Soup Task [47]

and CLOSE_FRIDGE. The experimental protocol will be more detailed with steps detailing the actions in the PASS as well as any side-actions that occur. Then, from the steps in the experimental protocol, the fine-grained actions can be extracted.
